Components of addiction and an 'emotional hardware' of the brain. This review seeks to explain both the neuromorphology and neurophysiology of the recently emergent concept of emotional memory. We base this concept on the postulate that alterations in the synaptic and cellular end-organ mechanisms that are engaged in the synthesis, storage and retrieval of cognitive memories are just as likely to be involved in any behavioral or pathological process. This proposes a parallel between 'cognitive' and 'emotional' memory in the brain, and a common mechanism for both. This should be a useful model for understanding the processes of addiction. We also raise the possibility that components of addiction reflect alterations in aspects of emotionality, and this may provide insight into the nature of the underlying neurophysiological changes. RNA binding proteins (RBPs) are abundant in eukaryotic cells and the number of RBPs has been predicted to exceed that of the genes they regulate. RBPs have emerged as key regulators of RNA splicing, export, localization, stability, and translation. The identification of protein:RNA interactions in vivo has been largely aided by the microscale discovery of RBPs by the high throughput immunoprecipitation (I) of individual RBPs or ribonucleoprotein (RNP) complexes from cell extracts followed by microsequencing of the co-purified RNAs. In cell extracts, these methods can be generalized to the topologically associated domain (1678ea9f9e
